Postestimation commands predict margins
Remarks and examples Methods and formulas Also see

# **Postestimation commands**

The following postestimation commands are available after zioprobit:

Command	Description
contrast	contrasts and ANOVA-style joint tests of estimates
estat ic	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
estat summarize	summary statistics for the estimation sample
estat vce	variance-covariance matrix of the estimators (VCE)
estat (svy)	postestimation statistics for survey data
estimates	cataloging estimation results
etable	table of estimation results
*forecast	dynamic forecasts and simulations
*hausman	Hausman's specification test
lincom	point estimates, standard errors, testing, and inference for linear combinations of coefficients
*lrtest	likelihood-ratio test
margins	marginal means, predictive margins, marginal effects, and average marginal effects
marginsplot	graph the results from margins (profile plots, interaction plots, etc.)
nlcom	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
predict	probabilities, linear predictions and their SEs, etc.
predictnl	point estimates, standard errors, testing, and inference for generalized predictions
pwcompare	pairwise comparisons of estimates
suest	seemingly unrelated estimation
test	Wald tests of simple and composite linear hypotheses
testnl	Wald tests of nonlinear hypotheses

<sup>\*</sup>forecast, hausman, and lrtest are not appropriate with svy estimation results.

## predict

### **Description for predict**

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

#### Menu for predict

Statistics > Postestimation

### Syntax for predict

statistic

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
  outcome(outcome) nooffset]

predict [type] stub* [if] [in], scores
```

Description

simisiic	Description
Main	
pmargin	marginal probabilities of levels, $Pr(y_j = h)$ ; the default
pjoint1	joint probabilities of levels and participation, $Pr(y_j = h, s_j = 1)$
pcond1	probabilities of levels conditional on participation, $Pr(y_j = h   s_j = 1)$
ppar	probability of participation, $Pr(s_j = 1)$
pnpar	probability of nonparticipation, $Pr(s_j = 0)$
хb	linear prediction
xbinfl	linear prediction for inflation equation
${\tt stdp}$	standard error of the linear prediction
${\tt stdpinfl}$	standard error of the linear prediction for inflation equation

If you do not specify outcome(), pmargin, pjoint1, and pcond1 (with one new variable specified) assume outcome(#1).

You specify one or k new variables with pmargin, pjoint1, and pcond1, where k is the number of outcomes.

You specify one new variable with ppar, pnpar, xb, xbinfl, stdp, and stdpinfl.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

## Options for predict

```
_____ Main
```

pmargin, the default, calculates the predicted marginal probabilities of outcome levels,  $\Pr(y_j = h)$ . pjoint1 calculates the predicted joint probabilities of outcome levels and participation,  $\Pr(y_j = h, s_j = 1)$ .

pcond1 calculates the predicted probabilities of outcome levels conditional on participation,  $Pr(y_j = h|s_j = 1)$ .

With pmargin, pjoint1, and pcond1, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, predict computes probabilities for the first outcome level. You can specify the outcome (#i) option to obtain probabilities for the ith level. When you specify multiple new variables or a stub, predict computes probabilities for all outcome levels. The behavior of predict with one new variable is equivalent to specifying outcome(#1).

ppar and pnpar calculate the predicted marginal probability of participation  $[Pr(s_i = 1)]$  and of nonparticipation  $[Pr(s_i = 0)]$ , respectively.

In health-related fields, probabilities of participation and nonparticipation are known as probabilities of susceptibility and nonsusceptibility. Similarly to predict after ziologit, you can use options ps and pns to compute these probabilities. Options ps and pns produce identical results to the respective options ppar and pnpar but label new variables as Pr(susceptible) and Pr(nonsusceptible) instead of Pr(participation) and Pr(nonparticipation).

xb calculates the linear prediction for the ordered probit equation, which is  $x_i\beta$  if offset() was not specified with zioprobit and is  $\mathbf{x}_{i}\boldsymbol{\beta} + \text{offset}_{i}^{\beta}$  if offset() was specified.

xbinfl calculates the linear prediction for the inflation equation, which is  $\mathbf{z}_i \gamma$  if offset() was not specified in inflate() and is  $\mathbf{z}_j \gamma + \text{offset}_i^{\gamma}$  if offset() was specified in inflate().

stdp calculates the standard error of the linear prediction for the ordered probit equation.

stdpinfl calculates the standard error of the linear prediction for the inflation equation.

outcome (outcome) specifies the outcome for which predicted probabilities are to be calculated. outcome() should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. outcome() is allowed only with pmargin, pjoint1, and pcond1.

nooffset is relevant only if you specified offset(varname) with zioprobit or within the inflate() option. It modifies the calculations made by predict so that they ignore the offset variable; that is, the linear prediction for the main regression equation is treated as  $\mathbf{x}_i \boldsymbol{\beta}$  rather than as  $\mathbf{x}_j \boldsymbol{\beta}$  + offset<sub>j</sub> and the linear prediction for the inflation equation is treated as  $\mathbf{z}_j \boldsymbol{\gamma}$  rather than as  $\mathbf{z}_{i}\boldsymbol{\gamma}$  + offset $_{i}^{\check{\gamma}}$ .

scores calculates equation-level score variables.

The first new variable will contain  $\partial \ln L/\partial(\mathbf{x}_i\beta)$ . In the absence of independent variables in the main equation, this variable is not stored.

The second new variable will contain  $\partial \ln L/\partial (\mathbf{z}_i \boldsymbol{\gamma})$ .

When the dependent variable takes k different values, the third new variable through new variable k+1 will contain  $\partial \ln L/\partial(\kappa_h)$  for  $h=0,1,\ldots,k-2$ .

# margins

## **Description for margins**

margins estimates margins of response for probabilities and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic	Description
default	marginal probabilities for each outcome
pmargin	marginal probabilities of levels, $Pr(y_j = h)$ ; the default
 pjoint1	joint probabilities of levels and participation, $Pr(y_i = h, s_j = 1)$
pcond1	probabilities of levels conditional on participation, $Pr(y_j = h   s_j = 1)$
ppar	probability of participation, $Pr(s_j = 1)$
pnpar	probability of nonparticipation, $Pr(s_i = 0)$
xb	linear prediction
xbinfl	linear prediction for inflation equation
stdp	not allowed with margins
stdpinfl	not allowed with margins

pmargin, pjoint1, and pcond1 default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

# Remarks and examples

Female

#### stata.com

Various sets of predictions and marginal effects may be of interest for the ZIOP model. For instance, we may want to investigate the marginal effects of a covariate on the probability of participation, or on the probabilities for levels of consumption conditional on participation, or on the overall probabilities for different consumption levels. We explore these options in greater detail in the following examples.

#### Example 1: Average marginal effects on probability of nonparticipation

In example 1 of [R] zioprobit, we fit a model for level of cigarette consumption.

```
. use https://www.stata-press.com/data/r18/tobacco
(Fictional tobacco consumption data)
. zioprobit tobacco education income i.female age,
> inflate(education income i.parent age i.female i.religion)
 (output omitted)
```

We can use margins to estimate the expected marginal effect of gender for individuals with a college degree (17 years of education) and a smoking parent on the probability of nonparticipation (being a genuine nonsmoker). To do this, we specify predict(pnpar) with margins as follows:

```
. margins, predict(pnpar) dydx(female) at(education = 17 parent = 1)
Average marginal effects
                                                         Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
dy/dx wrt: 1.female
At: education = 17
    parent
              = 1
                          Delta-method
                    dy/dx
                            std. err.
                                                 P>|z|
                                                            [95% conf. interval]
                                            z
      female
```

Note: dy/dx for factor levels is the discrete change from the base level.

.0100239

Women with a college degree and a smoking parent are expected to have about an 8.5% higher chance of being genuine nonsmokers than do men.

.105246

#### 1

## Example 2: Predicted probabilities of zero-valued outcomes

.0855995

In example 1 of [R] zioprobit, we found that the coefficient on income was positive in the level equation but negative in the participation equation. In the case of our tobacco consumption example, economic theory offers a reasonable interpretation for this. Higher income may act as an indicator for health awareness, which accounts for its association with an increased probability of being a genuine nonsmoker. However, if cigarettes are a normal good—that is, something for which demand increases when income increases—then smokers with higher income should have a lower probability of having zero consumption at the time of the survey.

We first consider the effect of income at six prespecified values ranging from \$10,000 to \$60,000 on the probability of being a genuine nonsmoker (nonparticipation). Because we know the values 1 to 6 correspond to income in tens of thousands, we conserve space and suppress the default legend by using the noatlegend option.

. margins, predict(pnpar) at(income = (1/6)) noatlegend

Predictive margins Number of obs = 15,000

Model VCE: OIM

Expression: Pr(nonparticipation), predict(pnpar)

	Margin	Delta-method std. err.	z	P> z	[95% conf.	interval]
_at						
1	.1727928	.0056963	30.33	0.000	.1616283	.1839573
2	.1944564	.0055236	35.20	0.000	.1836304	.2052824
3	.2176787	.0052981	41.09	0.000	.2072945	.2280629
4	.2424141	.0050413	48.09	0.000	.2325333	.2522948
5	. 2685948	.0047857	56.12	0.000	.259215	.2779745
6	.2961309	.0045767	64.70	0.000	.2871607	.3051011

The probability of being a genuine nonsmoker increases with income. For instance, for individuals who earn \$10,000 a year, the expected increase in the probability of being a genuine nonsmoker is about  $(0.1945 - 0.1728) \times 100\% = 2.17\%$  if they earn an additional \$10,000.

We next investigate the effect of income on the joint probability of being a smoker (participation equals 1) with zero consumption. We do this by specifying predict(pjoint1 outcome(0)) with margins:

. margins, predict(pjoint1 outcome(0)) at(income = (1/6)) noatlegend

Predictive margins Number of obs = 15,000

Model VCE: OIM

Expression: Pr(tobacco=0, participation=1), predict(pjoint1 outcome(0))

	Margin	Delta-method std. err.	l z	P> z	[95% conf.	interval]
1	.5595131	.0040167	139.30	0.000	.5516405	.5673856
2	.5080066	.0037793	134.42	0.000	.5005993	.5154139
3	. 4558656	.0035553	128.22	0.000	.4488975	.4628338
4	.4029089	.0033683	119.62	0.000	.3963072	.4095106
5	.3485692	.0032481	107.32	0.000	.3422031	.3549352
6	.2929155	.00317	92.40	0.000	.2867023	.2991287

For individuals who are smokers, the probability of zero consumption decreases as income increases, suggesting that tobacco is like a normal good for smokers. For example, for individuals who earn \$10,000 a year, earning an additional  $$10,000$ will decrease their probability of being a smoker with zero consumption by about <math>(0.5595-0.5080)\times100\%=5.15\%$ .

If we wanted to compute the effect of income on the overall probability of zero consumption instead of the probability of zero consumption among smokers, we would omit pjoint1 from within the predict option.

. margins, predict(outcome(0)) at(income = (1/6)) noatlegend
(output omitted)

This version of the margins command gives the sum of the probability of nonparticipation and the joint probability of participation with zero consumption.

### Methods and formulas

The participation equation is

$$s_j = I(\mathbf{z}_j \gamma + u_{1j} > 0)$$
  $j = 1, 2, \dots, n$ 

where  $s_j$  is 1 if the jth subject belongs to the participation group (for example, smokers) and is 0 if the subject belongs to the nonparticipation group (for example, genuine nonsmokers),  $\mathbf{z}_j$  are the covariates used to model the group membership,  $\gamma$  is a vector of coefficients, and  $u_{1j}$  is a random-error term following a standard normal distribution.

The ordinal outcome equation is

$$\widetilde{y}_j = \sum_{h=0}^{H} hI\left(\kappa_{h-1} < \mathbf{x}_j \boldsymbol{\beta} + u_{2j} \le \kappa_h\right)$$

where  $\widetilde{y}_j$  is the ordinal outcome conditional on participation,  $\mathbf{x}_j$  are the outcome covariates,  $\boldsymbol{\beta}$  are the coefficients, and  $u_{2i}$  is a random-error term following a standard normal distribution. The observed outcome values are 0, 1, ..., H.  $\kappa_0, \kappa_1, \ldots, \kappa_{H-1}$  are real numbers such that  $\kappa_i < \kappa_m$  for i < m.  $\kappa_{-1}$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ . We assume that the error terms  $u_{1j}$  and  $u_{2j}$  are independent. We observe  $y_j = s_j \widetilde{y}_j$ .

The probability of participation is

$$\Pr\left(s_{i} = 1 | \mathbf{z}_{i}\right) = \Phi\left(\mathbf{z}_{i} \boldsymbol{\gamma}\right) \tag{1}$$

where  $\Phi(\cdot)$  is the standard normal distribution function.

The probability of nonparticipation is

$$\Pr(s_j = 0 | \mathbf{z}_j) = 1 - \Phi(\mathbf{z}_j \gamma)$$
(2)

The probability of outcome  $y_j = h$  given that the jth subject belongs to the participation group is

$$Pr(y_j = h | s_j = 1, \mathbf{x}_j) = Pr(\widetilde{y}_j = h | \mathbf{x}_j)$$

$$= \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta})$$
(3)

for h = 0, 1, ..., H, where  $\Phi(\kappa_{-1} - \mathbf{x}_j \boldsymbol{\beta}) = 0$  and  $\Phi(\kappa_H - \mathbf{x}_j \boldsymbol{\beta}) = 1$ .

The joint probability of outcome  $y_j = h$  and participation can be expressed as

$$\Pr(y_j = h,\, s_j = 1 | \mathbf{z}_j, \mathbf{x}_j) = \Pr\left(s_j = 1 | \mathbf{z}_j\right) \Pr(y_j = h | s_j = 1, \mathbf{x}_j)$$

for  $h = 0, 1, \dots, H$ , and computed using (1) and (3).

The marginal probabilities of the outcome  $y_i$  are

$$\begin{split} & \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) = \Pr\left(s_j = 0 | \mathbf{z}_j\right) + \Pr\left(s_j = 1 | \mathbf{z}_j\right) \Pr(\widetilde{y}_j = 0 | \mathbf{x}_j) \\ & \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) = \Pr\left(s_j = 1 | \mathbf{z}_j\right) \Pr(\widetilde{y}_j = h | \mathbf{x}_j) \\ & \Pr(y_j = H | \mathbf{z}_j, \mathbf{x}_j) = \Pr\left(s_j = 1 | \mathbf{z}_j\right) \Pr(\widetilde{y}_j = H | \mathbf{x}_j) \end{split}$$

and can be computed using (1), (2), and (3).

If the offset() option is specified with zioprobit,  $\mathbf{x}_j \boldsymbol{\beta}$  is replaced with  $\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^{\boldsymbol{\beta}}$ . If the offset() option is specified within the inflate() option,  $\mathbf{z}_j \boldsymbol{\gamma}$  is replaced with  $\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^{\boldsymbol{\gamma}}$ .
